Introduction → Machine Learning Basics

Definition

A computer program learns from experience E with respect to tasks T, if its performance P improves with experience E.

This quite vague definition allows us to develop some intuition about the situation.

- **Experience** is given by an increasing sequence of observations, for example X_1, X_2, \ldots, X_t could represent the information at time t. This is typically decoded in a **filtration**: a filtration is an increasing sequence of sub- σ -fields $(\mathscr{F}_t)_{t \in \mathcal{T}}$.
- The performance is often measured in terms of an **utility function**. For example the utility at time t could be given by $U(X_t)$ with an function U. U could of course depend on more variables. One could also look for the accumulated utility

$$\sum_{t=1}^{T} U(X_t).$$

One very simple learning algorithm is linear regression, a classical statistical concept. Here it arises as an example of **supervised learning**.

Example (Linear Regression)

Suppose we oberseve pairs $(x_i, y_i)_{i=1,...,n}$ and want to predict y on basis of x. Linear regression requires

$$\hat{y}(x) = \beta x$$

with some weight $\beta \in \mathbb{R}.$ We specify a loss function $^{\mathbf{11}}$

$$\mathsf{RSS}(\beta) := \sum_{i=1}^n (y_i - \hat{y}(x_i))^2$$

and minimize over β .

One could choose -MSE as utility function. So how does the system learn?

¹¹Given by the Residual Sum of Squares here.

The system learns by maximizing the utility, i.e. minimizing the MSE for each n. And additional data will lead to a better prediciton. We will later see that this is in a certain sense indeed optimal.

We use the first-oder condition to derive the solution letting ${\boldsymbol x}=(x_1,\dots,x_n)$ and similar for ${\boldsymbol y}$,

$$0 = \partial_{\beta} (\boldsymbol{y} - \beta \boldsymbol{x})^{2} = \partial_{\beta} (\boldsymbol{y}^{2} - 2\boldsymbol{y}^{\top} \beta \boldsymbol{x} + \beta^{2} \boldsymbol{x}^{\top} \boldsymbol{x})$$

$$\Leftrightarrow 0 = -2\boldsymbol{x}^{\top} \boldsymbol{y} + 2\beta \boldsymbol{x}^{\top} \boldsymbol{x}$$

$$\Leftrightarrow \quad 0 = -2\boldsymbol{x} \cdot \boldsymbol{y} + 2\beta \boldsymbol{x} \cdot \boldsymbol{x}$$

such that we obtain

$$\hat{eta} = (oldsymbol{x}^{ op} oldsymbol{x})^{-1} oldsymbol{x}^{ op} oldsymbol{y}.$$

Note that typically one considers affine functions of x without mentioning, i.e. one looks at functions $y=\alpha+\beta x$. This can simply be achieved with the linear approach by augmenting x by an additional entry 1.

▶ Of course many generalizations are possible:

and many more.

- lacktriangle To higher dimensions: consider data vectors $(m{x}_i, m{y}_i)$, $i=1,\ldots,n$,
- \blacktriangleright To nonlinear functions: include x_i^1,\ldots,x_i^p into the covariates

Let us consider a linear regression in python.

```
import vfinance as vf
   import matplotlib.pyplot as plt
   DAX = vf.Ticker('%5Egdaxi')
   DAX History = DAX.history(start="2020-01-01", end="2020-10-26")
   plt.figure(figsize=(10,10))
   plt.plot(DAX History.index, DAX History['Close'])
   # Linear Regression example: regress tomorrow on today
   x = DAX History['Close'][:-1] # without the last value
   y = DAX_History['Close'][1:] # without the first value
   import numpy as np
                                                                DAY Price 2020
   from numpy import array
   from sklearn.linear model import Linea
   model = LinearRegression()
   x = array(x).reshape(-1,1)
                                  # The lir
   y = array(y).reshape(-1,1)
   model.fit(x, y) # values in model.int
   # Give a very sophisticated plot
   import seaborn as sns; sns.set_theme(
   ax = sns.regplot(x=x, v=v)
   plt.show()
                                                9000
                                                  2020-01 2020-02 2020-03 2020-04 2020-05 2020-06 2020-07 2020-08 2020-09 2020-10 2020-11
Could we improve this? Suggestions?

What is the difference to Statistics ?

In a statistical approach we start with a parametric model:

$$Y_i = \alpha + \beta x_i + \epsilon_i, \quad i = 1, \dots, n$$

and assume that $\epsilon_1,\ldots,\epsilon_n$ have a certain structure (for example, i.i.d. and $\mathcal{N}(0,\sigma^2)$). The one can derive (see, e.g. Czado & Schmidt (2011)) **optimal estimators** for α and β . One can also relax the assumptions and gets weaker results.

So what? What are the advantages of the statistical approach?

One particular outcome is that we are able to provide **confidence intervals**, **predictive intervals** and **test** hypothesises.

Questions

- What is the definition of Machine Learning?
- Give examples
- Give surprising examples
- ▶ Derive the main equation of linear regression
- (do it in 1 dimension first this goes back to Gauss)
- Write your own python code, providing a linear regression on your favourite stock
- Do this with your least favourite stock
- Can you regress two stocks on each other ?
- Can you predict better the value of the stock tomorrow ? (You can also research on this ...)
